Ethereum Is Profiting More From The Layer 2 Network Than Ever Before

Original:

<https://www.btcc.com/en-US/academy/research-analysis/ethereum-is-profiting-more-from-the-layer-2-network-than-ever-before>

Leasing security to Layer 2 networks has become a very profitable business for Ethereum.

Key Takeaways

- The Layer 2 network is spending more gas than ever before to settle transactions on the main Ethernet network.
- On Wednesday after the Optimism token launch, the Layer 2 network used a record 3.95% of Ether's daily gas consumption.
- Polygon's co-founder Sandeep Nailwal suggested on Twitter today that Ethereum might eventually evolve into a network where Layer 2 transactions occupy the majority of its blockspace.

As the Layer 2 network gains significant traction in user activity, the gasoline fees charged by Ether for renting its security are breaking new record highs.

Ethereum Is Earning More Money From Layer 2 Expansion

Layer 2 networks are spending record amounts of gas on Ethereum mainnet.

According to on-chain data from Dune, Layer 2 networks are now spending more gas than ever to settle or prove transaction batches on Ethereum's mainnet, with spending consistently surpassing 10 billion gas since the beginning on May.

For instance, the highest amount of gas ever used on the Ethereum mainnet to settle Layer 2 network transactions occurred this Wednesday—immediately after Optimism launched its OP governance token late Tuesday. Specifically, all Layer 2 networks combined spent around 3.95

billion of the total 100 billion daily gas limit on Ethereum, accounting for about 3.95% of the gas spent on the network that day. To put the growth rate into perspective, the total monthly gas spent by Layer 2 networks on Ethereum in May 2021 was around 5 billion, whereas in May this year, it was approximately 52 billion, marking over a tenfold increase in absolute gas usage terms.

When Ethereum traffic increases it accrues value to all [ETH](#) holders. This is because the base gas fees on Ethereum are burned, reducing the overall ETH supply and thus increasing the value of all remaining tokens. In this way Ethereum “profits” as Layer 2 networks use its blockspace to settle transactions more efficiently than can be done directly on mainnet.

Layer 2 is an umbrella term for [blockchain](#) scaling solutions that handle transactions on separate networks then send them back to Ethereum mainnet for settlement. For example, Optimism and Aribum are Layer 2 networks based on a cryptographic technology known as Optimistic Rollups that bundle transactions together off-chain (on their separate networks) and then settle the bundles in a single transaction on the Ethereum mainnet to reduce its transaction load.

Unlike so-called sidechains like Polygon’s Matic blockchain, which have their own consensus mechanisms, Layer 2 networks take the transactional load off of Ethereum but borrow or inherit its security by ultimately settling their batches on mainnet. This leads to an interesting dynamic where Layer 2 transactions become increasingly cheaper for users, but mainnet transactions remain sufficiently expensive to pay for Ethereum’s considerable security expenditure.

Commenting on the surge in Layer 2 usage on Twitter today, Polygon co-founder Sandeep Nailwal speculated that over time, Ether could evolve from a user-centric to a network-centric chain in which it primarily addresses bulk Layer 2 network transactions rather than individual, user-generated mainnet transactions. “As I also said before that #Ethereum is transitioning from a B2C(user to chain) business model to B2B(chain to chain) model,” he said, adding that eventually, “majority of the Eth’s gas would be used by L2 chains.”
